

Joins

Sql joins are the joins which we use to combine rows from two or more tables based on the related column

Ex :

Customers

Customer id – primary key

Name – Lokesh , mudit , sunanaya

Orders

Order id – primary key

Customer id – primary key of the customer table but it will be the reference key of the table another

Inner

Outer join

Right join

Left join

Full outer join

Self join

Cross join

Left join : returns all rows from the left table and matching rows from the right

Right join : all the rows from right table and matching rows from left

Full outer join : all rows from both tables + matching rows from the left

Cross join : every possible combination of rows

Self join : a table joined by itself

Inner join : only matching rows from both the tables

When to use which join :

Real world ex:

Inner join : most common (matching records only)

Left join : combine the data from left side

Right join : rarely used because you can usually rewrite the left join by swapping tables

Full outer join : data comparison , auditing

Cross join : occasionally for generating combinations

Self join : used when dealing with the hierarchical data such as employees and managers
